1 Memory Stall Cycles Calculations

Notions	Operations	Delay (cycle)
t_{sa}	Send the address	1
t_{al}	Access single cache content	2
t_{al1}	Access L1 cache content	1
t_{al2}	Access L2 cache content	10
t_{am}	Access memory content	100
t_{sw}	Send a word of data	1

1.1 One-word-wide memory organization

$$hit\_cycles = t_{sa} + t_{al} + t_{sw}$$
$$= 1 + 2 + 1 = 4$$
$$miss\_cycles = t_{sa} + 8 \times (t_{sa} + t_{am} + t_{sw} + t_{al}) + t_{al} + t_{sw}$$
$$= 1 + 8 \times (1 + 100 + 1 + 2) + 2 + 1 = 836$$

1.2 Wider memory organization

$$hit\_cycles = t_{sa} + t_{al} + t_{sw}$$
$$= 1 + 2 + 1 = 4$$
$$miss\_cycles = t_{sa} + (t_{sa} + t_{am} + t_{sw} + t_{al}) + t_{al} + t_{sw}$$
$$= 1 + (1 + 100 + 1 + 2) + 2 + 1 = 108$$

1.3 Two-level memory organization

$$hit\_cycles = t_{sa} + t_{al1} + t_{sw}$$
$$= 1 + 1 + 1 = 3$$
$$L1\_miss\_cycles = t_{sa} + (t_{sa} + t_{al2} + t_{sw} + t_{al1}) + t_{al1} + t_{sw}$$
$$= 1 + 4 \times (1 + 10 + 1 + 1) + 1 + 1 = 55$$
$$global\_miss\_cycles = t_{sa} + 32 \times (t_{sa} + t_{am} + t_{sw} + t_{al2}) + 4 \times (t_{sa} + t_{al2} + t_{sw} + t_{al1}) + t_{al1} + t_{sw}$$
$$= 1 + 32 \times (1 + 100 + 1 + 10) + 4 \times (1 + 10 + 1 + 1) + 1 + 1 = 3639$$

2 Results of Calculations

Testcases	Exe Cycles	One-word-wide	Wider	2-level
a1xb1	1553	6016	1648	12144
a2xb2	6141	19072	5968	32736
a3xb3	183925	7626560	1068008	791552
a4xb4	5781957	251426432	35098320	998152040

3 Differences among Memory Organizations

- Wider memory organization 因為有比較大的bandwidth 所以可以一次傳輸多個words 的data，減少data transfer 需要的cycles，而2 level memory organization 可以讓某些 在L1 或L2 hit 的address 以更少的cycles 傳輸給processor。

- We can see that increasing bandwidth indeed reduce the miss penalty (from 836 to 108). While with using L-2 cache, the L-2 miss penalty is much higher, so we need to focus on reducing miss rate to avoid total memory stall cycle higher then original memory organizations (Fig1.(a)).

4 Bonus

4.1 matmul.txt C++ style code

```
for (i = 0; i < m; i ++) {
    for (j = 0; j < p; j ++) {
        for (k = 0; k < n; k ++) {
            load C[i][j];
            load A[i][k];
            load B[k][j];
            do C[i][j] += A[i][k] * B[k][j];
            store C[i][j];
        }
    }
}
```

4.2 bonus_matmul.txt C++ style code

```cpp
for (i = 0; i < m; i ++) {
    for (j = 0; j < n; j ++) {
        load A[i][j];
        for (k = 0; k < p; k ++) {
            load C[i][k];
            load B[j][k];
            do C[i][k] += A[i][j] * B[j][k];
            store C[i][k];
        }
    }
}
```

4.3 Explanation

我們將load A[i][j] 提到第二層迴圈，這樣就可以將原來要load A[i][j] $m \times n \times p$ 次減少到$m \times n$ 次，減少require data 的次數。

4.4 Test and Delay Cycles Calculations for Bonus

Compiling: make bonus
Execution: ./simulate_caches [input_filename] [output_filename]
the output format is exactly the same as the original one.

4.5 Results of Bonus

Testcases	Exe Cycles	One-word-wide	Wider	2-level
a1xb1	1313	5824	1456	12000
a2xb2	4797	18176	5072	32064
a3xb3	142453	1032000	215912	454912
a4xb4	4555205	31508096	6719696	40791860
